}
```

2. **Which measure — vowel formants / VOT / rhythm metrics / Pillai / sibilant moments / distance-matrix-dendrogram:** Interval-based variability measures (rhythm metrics).

> Exact line from PDF: “Interval-based variability measures (Dellwo 2006, Low et al. 2000, Ramus et al. 1999) were employed to identify differences in durational variability across both speech styles and languages.”

3. **Normalization used — Lobanov or other?:** Coefficient of variation (Varco) and Normalized pairwise variability (nPVI).

> Exact line from PDF: “VarcoV (coefficient of variation of vocalic intervals, calculated as the standard deviation of vocalic interval duration divided by the mean and multiplied by 100)”.

4. **How the distance/clustering was built:** Statistical analysis using ANOVA models to compare speech styles and languages.

> Exact line from PDF: “we fitted an ANOVA model using the resulting scores of each measure… we compared speech styles (spontaneous vs. read speech) and languages (English vs. Japanese) for each measure”.

5. **Principal findings:** Spontaneous speech is more globally variable than read speech in English, but Japanese vocalic elements remain largely unaffected by speech style.

> Exact line from PDF: “the temporal variability of vocalic elements in Japanese is not affected by differences in speech style, although these differences still impact consonantal elements.”

6. **Foundational vs. applied:** Application (precedent for using durational variability to investigate cross-linguistic speech style effects).

7. **Tag:** Context-cite.

Paper 2: Van Der Donckt et al. (2024)

1. **Title / DOI / Year / Citations:** “Ecologically valid speech collection in behavioral research: The Ghent Semi-spontaneous Speech Paradigm (GSSP).” Year: 2024. DOI: https://doi.org/10.3758/s13428-023-02300-4

}
```

2. **Which measure:** openSMILE GeMAPSv01b acoustic features (temporal, frequency, and amplitude) and ECAPA-TDNN embeddings.

> Exact line from PDF: “The extraction of speech parameters was conducted using the openSMILE 3.0.1 Python API (Eyben et al., 2010) and the GeMAPSv01b functional configuration”.

3. **Normalization used — Lobanov or other?:** Z-score standardization and Yeo-Johnson power transformation.

> Exact line from PDF: “the features were standardized by removing the mean and scaling to unit variance.”

4. **How the distance/clustering was built:** t-SNE projection of embeddings and logistic regression for binary style classification.

> Exact line from PDF: “These embeddings were projected into a lower-dimensional space using t-distributed stochastic neighbor embedding (t-SNE)”.

5. **Principal findings:** GSSP speech is acoustically distinct from read-aloud speech (83% accuracy) and corresponds well to naturalistic interview speech (70% accuracy).

> Exact line from PDF: “acoustic analysis suggested that the acoustic properties of the GSSP correspond to those of spontaneous speech.”

6. **Foundational vs. applied:** Foundational/Method-defining (introduces the GSSP as an ecologically valid unscripted speech collection method).

7. **Tag:** Foundational-cite.
